

Problem

- Our application has three types of users.
- First type should have (username, email, bio)
- Second type should have (username, email, bio, certification file (title, file))
- Third type should have (username, email, bio, map location, date of birth)

Requirements

- Implement database structure for this part of the application
- Implement create user endpoint(s) - no authentication needed

Notes

- User certification includes a name and an image file or a pdf.
- Image should be loaded to the server before the main request.
- Consider application performance.
- Consider the design pattern (repository pattern is recommended)
